

AST4762: Astronomical Data Analysis

GitHub with Unix

When using Unix you can still use GitHub, but you will be doing so using your terminal. Before starting with this file, make sure you have read and practiced using Git locally with `learngit.pdf`. Also, note that since August 2021 you cannot use your password anymore when connecting to GitHub via a terminal, but will need a personal access token. You can find information on how to make one here:

<https://docs.github.com/en/authentication/keeping-your-account-and-data-secure/creating-a-personal-access-token>

Here we assume that you have made your `ast4762/` folder already (`mkdir ast4762`) and have moved in there the log file (go to the folder with `cd ast4762` and then `mv location_where_log_is/0-ast4762-yourname.log .`).

Initialize a git repo in `ast4762/` following the `learngit.pdf` (`git init`), add the log file to the repo (`git add`) and commit with an informative message (`git commit -m`).

Now we are going to connect your local git repository with GitHub. Got to GitHub on your favorite web browser. Make a new, empty repository named `ast4762`.

Now go back to your terminal. Type:

```
git remote add origin https://github.com/username.ast4762.git
```

don't forget to change `username` with your username! This connects your git repository with the `ast4762` repository in GitHub, which is now known as the 'origin'.

Push your local `ast4762/` repository (currently we assume you only added and committed the log file) to GitHub by typing:

```
git push origin master
```

This will prompt you to input your username (the GitHub username) and a password. Remember to use your personal token!

If you now go to the web browser and refresh the page you will see that your `st4762` folder has your log. From this point on, when you add and commit something else in your local git, you can again push it to origin by typing `git push origin master`. You are all set!
